

Virtual Machine Configuration & Ubuntu Account Recovery

Week 2 laboratory | Inspection date: 26 September 2026

DRAFT - NOT READY FOR SUBMISSION

Student name and section have not yet been supplied. Password recovery, successful login verification, Windows Server evidence, and the GitHub push remain outstanding.

1. Objective and scope

The laboratory guide asks students to install and configure Windows Server and Ubuntu Server in VirtualBox, document VM resources and major steps, and publish the documentation to GitHub. The student reports that the Ubuntu VM was already set up in Lab 1. This report records the existing configuration and the checks performed during this session.

2. Verified Ubuntu configuration

Setting	Observed value
VM name	ubuntu_server
Boot banner	Ubuntu 24.04.1 LTS
Memory / processors	2048 MB / 2 virtual CPUs
Virtual disk	VDI, 25.00 GB shown by VirtualBox
Network	NAT; adapter cable connected
Firmware / graphics	BIOS / VMSVGA, 16 MB video memory
Optical drive	Empty
Existing snapshot	Snapshot 1
Boot result	Console login prompt reached

Configuration difference: the guide requests a 30 GB Ubuntu disk; the existing disk is 25 GB. Its capacity was not changed. The snapshot name is verified, but its contents and clean-install status are not verified.

3. Configuration and boot evidence

Figure 1. Existing VirtualBox settings, showing RAM, CPUs, virtual disk, and NAT networking.

Figure 2. Ubuntu console after boot. Reaching a login prompt confirms that the guest boots; it does not establish a successful user login.

Verification performed

The registered Ubuntu VM was inspected and started in VirtualBox. It reached the Ubuntu 24.04.1 LTS console login prompt. An attempt was made to open the GRUB recovery menu during a restart, but the normal boot continued. No password change has yet been confirmed.

4. Installation history and evidence limits

The original installation predates this session. The supplied photographs describe the assignment; they do not show the student performing the installation. Original installation choices and screenshots cannot be reconstructed as observed facts. Only Ubuntu is currently registered in VirtualBox; the status of any Windows Server installation requires clarification.

5. Remaining completion steps

- Open the Ubuntu GRUB recovery menu, identify the existing user account, and complete the password reset.
- Sign in to Ubuntu and capture evidence of the successful login. Verify networking and the OpenSSH service.
- Supply the student name, section, and GitHub repository destination.
- Confirm Windows Server status and supply its configuration and login evidence where applicable.
- Add original installation screenshots if available, then finalize the PDF and Markdown notes.
- Commit the report and screenshots under week2 and push to the confirmed GitHub repository.

6. Current conclusion

The existing Ubuntu VM boots to its login prompt and has 2 GB RAM, 2 virtual CPUs, and NAT networking. The disk is smaller than the guide specifies. Account access, network service operation, and the Windows Server portion remain unverified. The lab is therefore not yet complete.

Source and repository status

Source: student-supplied photographs of the IT 123 - Week 2 Laboratory Guide. The guide requires a PDF report, installation documentation, screenshots, a configuration summary, and a GitHub upload.

Local evidence is saved under week2/screenshots and notes under week2/lab_notes.md. The current repository has no remote configured. No commit or push has been performed. Credentials and VM disk images are excluded from the intended upload.
